THIS PAGE BLANK (USPTO)

LC controllable oscillator, a quadrature oscillator and a communication arrangement

EPO - DG 1

12.02.2001

(59)

The invention relates to a LC controllable oscillator (LCCO) comprising a voltage controlled oscillator (VCO), a first voltage controlled current source (VCCS) of a first type for supplying a current to the VCO, the VCO being realized with a first pair of VCCS of the first type coupled with a second pair of VCCS of a second type and a LC resonator adapted to be controlled for generating a periodical oscillation frequency which is controllable by a control signal (V), further comprising a first (SUP) conductor and a second (REF) conductor for connection to an external direct voltage source (VS).

The invention further relates to a module and an arrangement that uses the LCCO.

The following is defined in this description: if a VCCS of the first type is considered that sources its output current then a VCCS of the second type sinks its output current. Furthermore, if a VCCS of the first type is considered that sinks its output current then a VCCS of the second type sources its output current.

LC oscillators are well known circuits that are used in a large spectrum of applications for generating periodical signals. When they are used in high frequency applications as optical fiber networks, mobile telephony, transceivers and many others, they must provide, among other qualities, a good stability of the periodical signals versus temperature modification, they must be controllable over a wide frequency range of the periodical signals, and so on.

The LC oscillators are preferred in high frequency applications because of their frequency accuracy and reduced phase margin noise they exhibit. These LC oscillators have as their main components a pair of active devices, transistors for example and a LC tank circuit that determines their oscillation frequency.

Such an oscillator is disclosed in US-A-5959504. It comprises a first pair of CMOS transistors with a tunable voltage applied to the back gate terminals for varying the parasitic capacitance of the transistor pair. The circuit further comprises a current generating means or a second transistor pair having a similar configuration but of opposite polarity to

the first transistor pair that is connected to the first transistor pair and across an inductor. The frequency of the oscillation is determined by the product between the inductor inductance and the parasitic capacitance of the first pair of transistors. It should be pointed out here that the oscillation frequency is determined by technology dependent parameters as the CMOS parasitic capacitance and the frequency is controlled with a voltage applied at the back gate of the CMOS transistors, being dependent on a specific type of active device. Furthermore no measures are considered for thermally compensation of the oscillator.

10 It is therefore an object of the present invention to provide a LC oscillator with means to improve the temperature behavior of the frequency of the oscillation, the frequency of oscillation being determined independently of the technology.

In accordance with the invention this is achieved in a device as described in introductory paragraph characterized in that the LCCO further comprises a replica scaled bias module (RSBM) supplied from the external voltage source via the first conductor (SUP) and the second conductor (REF), the RSBM being conceived to generate a control signal (BIAS CONTROL) for controlling the supplied current delivered by the first VCCS to the VCO.

The LCCO according to the invention has the advantage of a frequency independent of technology and a better thermal stabilization.

20 In an embodiment of the invention the RSBM comprises a second, a third and a fourth VCCS, the second and the third VCCS being of the first type, the fourth VCCS being of the second type.

The VCCS used in the RSBM are replicas at a different scale of that used in the VCO, the currents circulating through them being proportional to each other. For example, if a current sourced or sunk by a VCCS is I_0 then the replica scaled VCCS sources or sinks a current I_0/m , m being the scale factor.

25 The BIAS CONTROL signal modifies in the same way the supply current of the VCO and it's replica current in the RSBM module with the process and temperature variations. In this way the common mode voltage of the first pair of VCCS and of the second pair of VCCS is maintained constant. This improves the thermal stability and the phase noise margin of the LCCO.

30 In an embodiment the RSBM further comprises a current source of the first type coupled with a fifth VCCS of second type for providing a reference voltage to a first input of a differential voltage controlled voltage source (VCVS).

A second input of the VCVS is coupled with the fourth VCCS for supplying the signal (BIAS CONTROL) for controlling the supplied current in the VCO.

It should be pointed out here that the current source and the fifth VCCS may be regarded as a band gap reference voltage source that provides a better temperature behavior of the circuit. Furthermore, if the control signal V is generated using this band gap reference voltage, the oscillation frequency stability versus temperature is improved, too.

In a preferred embodiment of the invention, a LC tank circuit determines the frequency of oscillation that is controlled by an external control signal (V). The L and C components of the tank circuit have their inductance and capacitance much bigger than any other parasitic inductance and capacitance in the circuit and, as a matter of consequence, the oscillation frequency is determined independently of the technology.

It should be pointed out here that depending on the type the L and C components of the LC tank circuit it's oscillation frequency can be controlled electrically, mechanically, thermally, optically.

Illustratively, all the previously described stages may be realized with transistors and LC tank resonators. In an embodiment all these transistors may be implemented in CMOS technology.

It is another object of the present invention to provide a module comprising the LCCO coupled with a phase shifter, controlled by the control signal (V), the phase shifter providing a first intermediate signal (S1) and a second intermediate signal (S2) to an adder (SUM), in which the intermediate signals S1 and S2 are added to each other for obtaining a signal (S) that is amplified by a first wide band amplifier (TIA) obtaining a first output signal (I), and to a subtraction circuit (DIF) where the intermediate signals S1 and S2 are subtracted from each other for obtaining a signal (D) that is amplified by a second wide band amplifier for obtaining a second output signal (Q).

The module is characterized in that the signals S1 and S2 are mutually phase shifted with 90 degrees.

The module is further characterized in that the output signals (I) and (Q) are periodical and mutually in quadrature.

Furthermore it is another object of the present invention to provide a communication arrangement for communicating via a bi-directional communication channel, characterized in that it comprises a receiver that comprises a data and clock recovery (DCR) circuit comprising a module as claimed in Claim 6, the receiver being arranged for generating an output vector of signals by combining a received signal (IN) received from the channel

with the periodical signals (I) and (Q), the arrangement further comprising an emission module for emitting an emission signal (OUT) to the channel, the emission module generating the emission signal by combining the periodical signals (I) and (Q) with an input signal vector (IN1) in a phase locked loop (PLL) circuit that contains the module.

5 The above and other features and advantages of the invention will be apparent from the following description of exemplary embodiments of the invention with reference to the accompanying drawings, in which:

10 Fig. 1 depicts a block diagram of a LC controllably oscillator (LCCO), according to the invention,

 Fig. 2 depicts a more detailed diagram of the LCCO according to the invention,

 Fig. 3 depicts a CMOS implementation of the LCCO according to one
15 embodiment of the invention,

 Fig. 4 depicts a module that uses a LCCO,

 Fig. 5 depicts a communication arrangement for communicating via a bi-directional channel,

 Fig. 6 depicts an interleaved phase/frequency detector in another embodiment
20 of the invention.

 Fig. 1 shows the block diagram of a LC controllably oscillator (LCCO), according to the invention. There is a voltage controlled oscillator (VCO) 102 which is
25 supplied with a current 104 via a VCCS 101 of a first type. The current 104 is controlled by a signal BIAS CONTROL supplied by a Replica Scaled Bias module (RSBM) 103. There are also provided two wires, a first wire labeled SUP and a second wire labeled REF to realize a connection between the LCCO and an external direct current source 105. A control signal V controls the oscillation frequency of the LCCO. If the VCCS 101 sources it's output current
30 then the SUP wire is connected to the positive node of the source 105 and the wire REF is the negative node of the source 105. If the VCCS 101 sinks it's output current then the SUP wire is connected to the negative node of the source 105 and the wire REF is the positive node of the source 105.

Fig. 2 depicts a more detailed diagram of the LCCO according to the invention. The VCO 102 is realized with a first pair 301 of VCCS of the first type and a second pair (302) of VCCS of the second type, comprising a resonator realized, for illustrative purposes, with a LC tank circuit that determines it's oscillation frequency. It is provided a control signal V that controls the oscillation frequency of the LCCO. For illustrative purposes, the control signal is a voltage, but depending on the practical devices used in the LCCO, it's oscillation frequency can be modified mechanically, optically, thermally. The LCCO further comprises the RSBM 103 comprising a differential voltage controlled voltage source (VCVS) 206 having a first input I1 and a second input I2 and delivers at it's output a signal BIAS CONTROL that controls the supply current 104 of the VCO 102 via the VCCS 101. A current source 205 of the first type coupled with a fifth VCCS 204 of the second type in order to provide a first reference voltage at the first input I1 of the VCVS 206. The BIAS CONTROL signal also controls a current 207 provided by a second VCCS 201 of the first type that is coupled with a third VCCS 202 of the second type, the third VCCS 202 being coupled with a fourth VCCS of the second type 203 and the second input terminal of the VCVS 206. The VCCS used in the RSBM are replicas at a different scale of that used in the VCO, the currents circulating through them being proportional each other. For example, if a current sourced or sinked by a VCCS is $2I_0$ then the replica scaled VCCS sources or sinks a current $2I_0/m$, m being the scale factor. In the case of the circuit depicted in the Fig. 2 the current 207 is the replica scaled of the current 104.

Fig. 3 depicts a CMOS implementation of the LCCO according to one embodiment of the invention. For illustrative purposes, CMOS transistors were used. However, the circuit may be implemented either in bipolar, CMOS or BiCMOS technologies, or a combination there of. For bipolar transistors, the control electrode, first main electrode and second main electrode correspond to the base, emitter and collector, respectively. For MOS transistors, the control electrode, first main electrode and second main electrode correspond to the gate, source and drain, respectively.

The first VCCS 101, the second VCCS 201 and the third VCCS 202 are p-MOS transistors, but any other VCCS of the first type can be used instead. The fourth VCCS 203 and the fifth VCCS 204 are n-MOS transistors but any other VCCS of the second type can be used instead. The differential VCVS 206 is an operational amplifier but any other differential VCVS can be used instead as, for example, an operational transconductance amplifier ended on a capacitor, or any other equivalent solutions.

The current 207 through the second VCCS is $2I_0/m$ and the current through the fifth VCCS 204 is I_0/m . Under this circumstances, the BIAS CONTROL signal generated by the VCVS 206 is proportional to I_0/m which is a replica scaled current that flows through the first pair 301 of VCCS and the second pair 302 of VCCS in the VCO 102. In this preferred
5 embodiment of the invention the scaling is obtained using transistors with the same length and with their width scaled with a factor m .

The BIAS CONTROL signal modifies in the same way the supply current 104 of the VCO 102 and the replica current 207 in the VCCS 201 with the process and temperature variations. In this way the common mode voltage of the first pair (301) of VCCS
10 and of the second pair (302) of VCCS is maintained constant. This improves considerably the phase noise margin, too. It should be pointed out here that the current source 105 and the fifth VCCS (204) may be replaced with a band gap reference voltage source that provides a better temperature behavior of the circuit. Furthermore, if the control signal V is generated using this band gap reference voltage, the oscillation frequency stability versus temperature is
15 improved, too.

Fig. 4 depicts a module 300 that uses a LCCO, which is essentially a quadrature oscillator. In the module 300 the LCCO 1 is coupled with a phase shifter 301 and they are controlled simultaneously by the same control signal V . The phase shifter 301 provides a first $S1$ and a second $S2$ intermediate signals at it's outputs that are mutually in
20 quadrature. The phase shifter can be realized as a controllable all pass filter but any other controllable quadrature phase shifter can be used instead. The intermediate signals $S1$ and $S2$ are used as input signals in an adder SUM 302 obtaining a signal S and in a subtractor DIF 303 obtaining a signal D . The S signal is amplified with a first amplifier TIA 304 obtaining an output signal I and the signal D is amplified with a second amplifier TIA 305 obtaining an
25 output signal Q . The two output signals are mutually in quadrature and, under these circumstances, the module 300 is a quadrature oscillator. In a preferred embodiment of the module the TIA 304 and 305 are disclosed in PH-NL010020EPP.

Fig. 5 depicts a communication arrangement 400 for communicating via a bi-directional channel 404. The communication arrangement is characterized in that it comprises
30 a receiver 401 that comprises a data and clock recovery DCR circuit 402 comprising the module 300, the receiver being arranged for generating an output vector of signals $OUT1$ by combining a received signal IN , received from the channel 404, with the periodical signals I and Q , the arrangement further comprising an emission module 403 for emitting an emission signal OUT to the channel 404, the emission module generating the emission signal by

combining the periodical signals I and Q with an input signal vector IN1 in a phase locked loop PLL circuit 405 that contains the module 300.

In a preferred embodiment of the invention, the output vector OUT1 is a vector of signals obtained in a Low IF/Zero IF receivers, SONET /SDH applications, the input vector of signals IN1 is a suitable coded analogical signal, the bi-directional communication channel 404 is an optical network and the arrangement 400 is a transceiver used in optical communication networks.

Fig. 6 depicts an interleaved phase/frequency detector in another embodiment of the invention. The LCCO 300 output signals I and Q are coupled with a first and a second D flip-flops (DFF) 500. The first DFF (500) has an input D1 coupled with an input signal DATA and a Clock input Ck1 coupled with the signal I from the LCCO generating a signal at an output terminal Q1 which is almost in phase with the positive edge of the signal I. The second DFF (500) has an input D2 coupled with an input signal DATA and a Clock input Ck2 coupled with the signal Q from the LCCO generating a signal at an output terminal Q2 which is almost in phase with the positive edge of the I signal. The phase/frequency detector is a part of the DCR 402 and the PLL 405. Furthermore the signal DATA is a component either of vector IN1 or IN.

It is remarked that the scope of protection of the invention is not restricted to the embodiments described herein. Neither is the scope of protection of the invention restricted by the reference numerals in the claims. The word 'comprising' does not exclude other parts than those mentioned in a claim. The word 'a(n)' preceding an element does not exclude a plurality of those elements. Means forming part of the invention may both be implemented in the form of dedicated hardware or in the form of a programmed general purpose processor. The invention resides in each new feature or combination of features.

THIS PAGE BLANK (USPTO)

CLAIMS:

(59)

1. A LC controllable oscillator (LCCO) (1) comprising
- a voltage controlled oscillator (VCO) (102), a first voltage controlled current
source (VCCS) of a first type (101) for supplying a current (104) to the VCO (102), the VCO
being realized with a first pair (301) of VCCS of the first type coupled with a second pair
5 (302) of VCCS of a second type and a LC resonator adapted for generating a periodical
oscillation frequency which is controllable by a control signal (V),

- a first (SUP) conductor and a second (REF) conductor for connection to an
external direct voltage source (105) characterized in that

- the LCCO (1) further comprises a replica scaled bias module (RSBM) (103)
10 supplied from the external voltage source (105) via the first conductor (SUP) and the second
conductor (REF),

- the RSBM (103) is conceived to generate a control signal (BIAS
CONTROL) for controlling the supplied current (104) delivered by the first VCCS (101) to
the VCO (102).

15

2. A LCCO (1) as claimed in Claim 1 wherein the RSBM (103) comprises a
second (201), a third (202) and a fourth (203) VCCS, the second and the third VCCS being of
the first type, the fourth VCCS being of the second type.

20 3. A LCCO (1) as claimed in Claim 1 in which the RSBM (103) further
comprises a current source of the first type (205) and a fifth VCCS of the second type (204)
that are coupled in a first input node (I1) of a differential voltage controlled voltage source
(VCVS) (206) that further comprises a second input (I2) that is coupled with the fourth
VCCS (203) for supplying the signal (BIAS CONTROL) for controlling the supply current
25 (104) in the VCO (102).

4. A module (300) comprising a LCCO (1) as claimed in Claim 1 coupled with a
phase shifter (301), controlled by the control signal (V), the phase shifter (301) being
conceived to provide a first intermediate signal (S1) and a second intermediate signal (S2) to

an adder (SUM) (302), for adding the intermediate signals S1 and S2 to each other for obtaining a signal (S) to be supplied to a first wide band amplifier (TIA) (304) for obtaining a first output signal (I), and to a subtraction circuit (DIF) (303) for subtracting the intermediate signals S1 and S2 from each other for obtaining a signal (D) to be supplied to a second wide
5 band amplifier (TIA) (305) for obtaining a second output signal (Q).

5. A module (300) as claimed in Claim 5 characterized in that the signals S1 and S2 are mutually phase shifted with 90 degrees.

10 6. A module (300) as claimed is Claim 6 characterized in that the output signals (I) and (Q) are periodical and mutually in quadrature.

7. A communication arrangement (400) for communicating via a bi-directional communication channel (404), characterized in that it comprises a receiver (401) that
15 comprises a data and clock recovery (DCR) circuit (402) comprising a module (300) as claimed in Claim 6, the receiver being arranged for generating an output vector of signals (OUT1) by combining a received signal (IN) received from the channel (404) with the periodical signals (I) and (Q), the arrangement further comprising an emission module (403) for emitting an emission signal (OUT) to the channel (404), the emission module being
20 conceived to generate the emission signal by combining the periodical signals (I) and (Q) with an input signal vector (IN1) in a phase locked loop (PLL) circuit (405) that contains the module (300).

ABSTRACT:

(59)

A LC controllable oscillator (LCCO) according to the invention comprises a voltage-controlled oscillator (VCO) and a first voltage controlled current source (VCCS) of a first type for supplying a current to the VCO. The VCO is realized with a first pair of VCCS of the first type coupled with a second pair of VCCS of a second type and a LC resonator.

- 5 The VCO generates a periodical oscillation frequency that is controllable by a control signal (V). The LCCO further comprises a replica scaled bias module (RSBM) supplied from the external voltage source. The RSBM is conceived to generate a control signal (BIAS CONTROL) for controlling the supplied current delivered by the first VCCS to the VCO.
